

Practical 1

Aim: To search a number from the list using linear method.

Theory: The process of identifying or finding a particular record is called searching. There are two types of search:

Linear Search

Binary Search

The Linear search is further classified as:

SORTED

UNSORTED

Here we will look on the UNSORTED LINEAR SEARCH.

Linear search also known as sequential search is a process that checks every element in the list sequentially until the desired element is found. When the elements to be searched are not specifically arranged in random manner. That is what it calls unsorted linear search.

The data is entered in random manner. User needs to specify the element to be searched in the entered list.

Check the cond" that whether the entered number matches if it matches then displaying the location plus increment 1 as data is stored from location zero.
IF all elements are checked or by one and elements not found then prompt message number not found.

32

N
1

```
found=False
a=[1,64,3,4,8,65,84,54,10,4]
search=int(input("enter the number search"))
for i in range(len(a)):
    if (search==a[i]):
        print("number is found at place",i+1)
        found=True
        break
if (found==False):
    print("number dose not exist")
print("shubhang 1776")
```

enter the number search
number is found at place 4

Aim:

Theory

Practical 2

Aim: To search a number from the list using

Theory: SEARCHING and SORTING are different modes on types of data-structure

SORTING:- To basically SORT the inputted data in ascending

or descending manner.

SEARCHING:- To search element and to display the same.

In searching that too in LINEAR SORTED search the data is arranged in ascending to descending or vice versa. That is all what it meant by searching through 'sorted' that is well arranged data.

MS
F

18

SORTED Linear search

The user is supposed to enter data in sorted manner.

User has to give an element for through sorted list.

If element is found display with an updation as value is stored from location '0' If data or element not found print the same.

In sorted order list of element we can check the condition that whether the entered number lies from starting point till the last element if not then without any processing we can say number not in the list.

Ans

```
found=False  
a=[11,12,13,14,15,26,27,67,68,80]  
print("shubhang 1776")  
search=int(input("enter the number search"))  
if(search<a[0] or search>a[len(a)-1]):  
    print("number dose not exist")  
else:  
    for i in range(len(a)):  
        if(search==a[i]):  
            print("number found at",i)  
            found=True  
            break  
    if(found==False):  
        print("number dose not exist")
```

```
shubhang 1776  
enter the number search13  
number found at 2  
>>> |
```

Practical 3: Binary Search

Aim: To search a number from the given sorted list using binary search.

Theory: A binary search, also known as a half interval search, is an algorithm used in computer science to locate a specified value (key) within an array. The array must be sorted in either ascending or descending order.

At each step of the algorithm a comparison is made and the procedure branches into one of two directions.

Specifically, the key value is compared to the array.

If the key value is less than or greater than this middle element, the algorithm known which half of the array to continue searching because the array is sorted.

This process is repeated on progressively smaller segment of the array until the value is located.

Binary search will complete successfully in logarithmic time.

98

```
a=[57,58,59,72,75,79,83,85]
print("shubhang 1776")
search=int(input("enter the number search"))
l=0
r=len(a)-1
while True:
    m=(l+r)//2
    if(l>r):
        print("number not found")
        break
    if(search==a[m]):
        print("number is found",m,"index number")
        break
    else:
        if(search<a[m]):
            r=m-1
        else:
            l=m+1
```

Aim: To

Theory:

Practical - 4

Aim:- To demonstrate the use of stack.

Theory:

In computer science, a stack is a abstract data type that serves as a collection of elements with two principal oprn. push, which adds an element to the collection and pop, which removes the most recently added element that was not yet removed. The order may be LIFO (last In first out) or FILO (First in Last out)

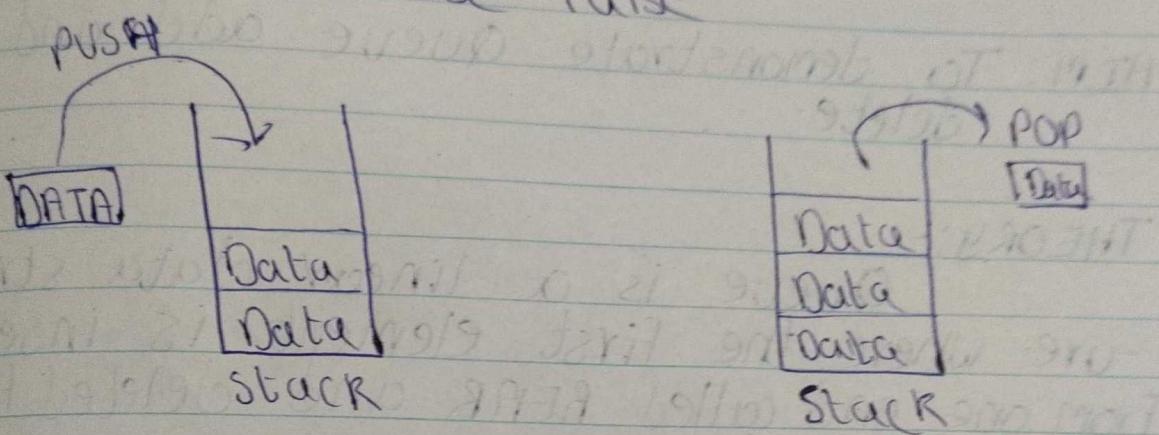

Three Basic operation are performed in the stack

- PUSH :- Adds an item in the stack. If the stack is full then it is said to be over flow condition

- POP :- Removes an item from the stack. The items are popped in the reverse order which they are pushed. If the stack is empty it is said to be under flow cond.

- PEEK or TOP :- Return top element of stack.

- is empty: Returns true if stack is empty
else False

LIFO (Last In First Out)

Q8

PROGRAM:

34

```

##stack##

print("shubhang 1776")

class stack:

    global tos

    def __init__(self):
        self.l=[0,0,0,0,0,0]
        self.tos=-1
        s.push(30)

    def push(self,data):
        n=len(self.l)
        if self.tos==n-1:
            print("STACK IS FULL")
            s.push(40)
        else:
            self.tos=self.tos+1
            self.l[self.tos]=data

AIM: To demonstrate Queue add and delete.

THEORY:-

Queue is a linear data structure where the first element is inserted from one end called REAR and deleted from the other end as FRONT.

Front points to the beginning of the queue and rear points to the end of the queue.

Queue follows the FIFO (First_in First_out) structure.

According to its FIFO structure element inserted first will also be removed first.

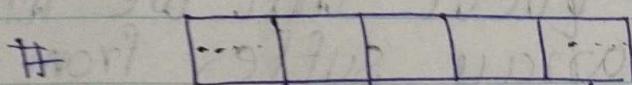

In a queue, one end is always used to insert data (enqueue) and the other is used to delete data (dequeue) because queue is open at both of its ends.

Enqueue() can be termed as add() in queue i.e add a element in queue.

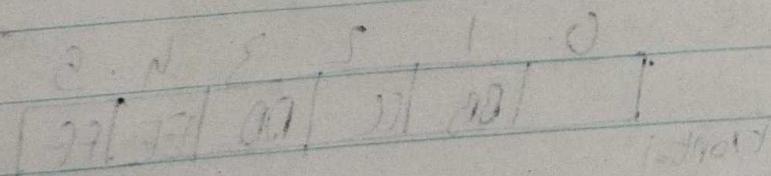

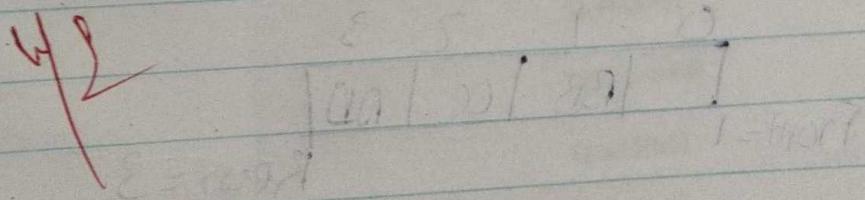

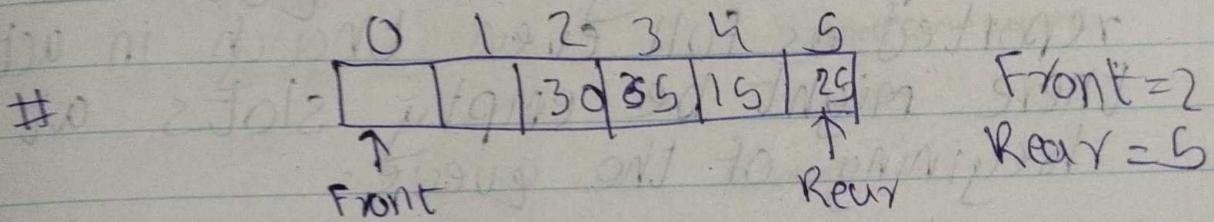

Dequeue() can be termed as delete or remove i.e deleting or removing of element.

front is used to get the front data item from a queue if start from 0 then

Rear is used to get the last item from a queue

on a queue can have ends both side

PROGRAM:

```
## Queue add and Delete ##
```

```

Practical-6

AIM: To demonstrate the use of circular queue in data-structure

Theory:-

The queue that we implement using an array suffer from one limitation. In that implementation there is a possibility that queue is reported as full even though in actual there might be empty slots at the beginning of the queue.

Example

| 0 | 1 | 2 | 3 | 4 | 5 |
|-----|----|----|----|----|---|
| XXX | CC | NN | EE | FF | |

Front = 2 Rear = 0

45

```

class Queue:
    global r
    global f
    def __init__(self):
        self.r=0
        self.f=0
        self.l=[0,0,0,0,0]
    def add(self,data):
        n=len(self.l)
        if self.r<=n-1:
            self.l[self.r]=data
            print("data added:",data)
            self.r=self.r+1
        else:
            s=self.r
            self.r=0
            if self.r<self.f:
                self.l[self.r]=data
                self.r=self.r+1
            else:
                self.r=s
                print("Queue is full")
    def remove(self):
        n=len(self.l)
        if self.f<=n-1:
            print("data removed:",self.l[self.f])
            self.f=self.f+1
        else:
            s=self.f
            self.f=0
            if self.f<self.r:
                print(self.l[self.f])
                self.f=self.f+1
            else:

PRACTICAL-8

Aim: To evaluate postfix expression using stack

THEORY: Stack is an (ADT) and works LIFO i.e PUSH & POP operation is placed after the operand.

Steps to be followed:

1. Read all the symbols one by one from left to right in the given postfix expression.
2. If the reading symbol is operand then push it on to the stack.
3. If the reading symbol is operator (+, -, *, /, etc.) then perform TWO operation and store the two popped operands in two different variables (operand 1 & operand 2). Then perform reading symbol operation using operand 1 & operand 2 and push result back on to the stack.
4. Finally, perform a pop operation and display the popped value as final result.

Value of postfix expression:

$$S = 12 \ 3 \ 6 \ 4 \ - \ + \ * \ 5 \ 11$$

Stack

| | |
|----|-----------------|
| 4 | $\rightarrow a$ |
| 6 | $\rightarrow b$ |
| 3 | |
| 12 | |

$$b-a = 6-4=2 \text{ // store again in stack}$$

| | |
|----|-----------------|
| 2 | $\rightarrow a$ |
| 3 | $\rightarrow b$ |
| 12 | |

$$b+a = 3+2 = 5 \text{ // store result in stack}$$

| | |
|----|-----------------|
| 5 | $\rightarrow a$ |
| 12 | $\rightarrow b$ |

$$b*a = 12 * 5 = 60$$

Practical - 9

Aim:- To sort given random data by using bubble sort

Theory:- SORTING is type in which any random data is sorted ie arranged in ascending or descending order.

Bubble Sort sometime referred as sinking sort
It is a simple sorting algorithm that repeatedly steps through the lists, compares adjacent elements and swaps them if they are wrong order.

The pass through the list is repeated until the list is sorted.

The algorithm which is a comparison sort is named for the way small or larger elements "bubble" to the top of the list.

Example:

First pass

(5 1 4 2 8) \rightarrow (1 5 4 2 8) Here algo compare the first two elements and swaps since $5 > 1$

Second pass:

47

(1 5 4 2 8) \rightarrow (1 4 5 2 8) Swap since (5 > 4)
(1 4 5 2 8) \rightarrow (1 4 2 5 8) Swap since (5 > 2)
(1 2 4 5 8) \rightarrow 1 2 4 5 2

Third pass

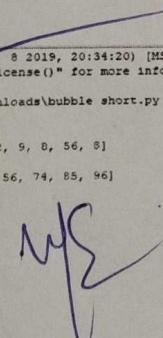

(1 2 4 5 8) It checks and gives
the data in sorted order.

WE

```

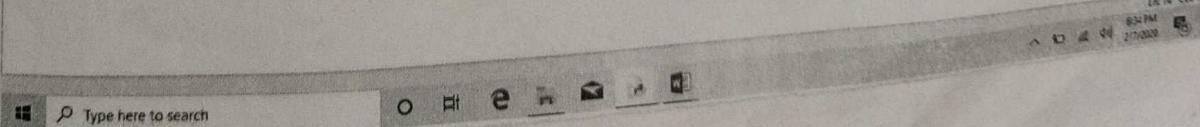

a=[12,1,6,5,85,4,6,74,8,0,96,4,2,9,8,56,8]
print("unsorted number is:\n")
print(a)
for i in range (len(a)-1):
    for j in range (len(a)-1-i):
        if (a[j]>a[j+1]):
            t=a[j]
            a[j]=a[j+1]
            a[j+1]=t
    print("sorted number is :\n",a)
print("\n\n\nshubhang 1776")

Practical - 10
Aim :- To sort using a) Merge sort

Theory :-

Merge sort is a divide and conquer algorithm based on the idea of breaking down list into several sub-lists until each sublists consist of a single element and merging those sublist in a manner that results into a sorted list.

While comparing two sublists is taken into consideration. While sorting is ascending order the element that is of lesser value becomes a new element of the sorted list. The procedure is repeated until both the smaller sublists are empty and new combine sublist comprise of all elements of both the sublist.

Practical - 11

Aim:- To sort using Selection Sort

Theory :-

The selection sort algorithm sorts an array by repeatedly finding the minimum element (considering ascending order) from unsorted part and putting it at the beginning.

The algorithm maintains two subarray in a given array.

- i) The subarray which is already sorted.
- ii) Remaining subarray which is unsorted.

In every iteration of selection sort, the minimum element (considering ascending order) from the unsorted subarray is picked & moved to the sorted subarray.

```
##Selection Sort##  
print ("Shubhang Singh")  
a=[10,12,16,14,15]  
print(a)  
  
for i in range (len(a)-1):  
    for j in range (len(a)-1):  
        if(a[j]>a[i+1]):  
            t=a[j]  
            a[j]=a[i+1]  
            a[i+1]=t  
    print (a)
```

Page

Aim:- Binary Tree

Theory:-

Binary tree is a tree which supports maxn of 2 children for any node within the tree thus any particular node can have either 0 or 1 or 2 children.

Leaf Node:- Nodes which do not have any children.

Internal Node:- Nodes which are non-leaf nodes

Traversing can be defined as a process of visiting every node of the tree exactly once

Preorder :- i) Visit the root node.

ii) Traverse the left subtrees. The left subtree in turn might have left and right subtrees

iii) Traverse the right subtree. The right subtree in turn might have left and right subtree

Inorder :- i) Traverse the left subtree. The left subtree in turn might have left and right subtree

ii) Visit the root node

iii) Traverse the right subtree right

subtree inturn might have left and right subtrees.

- Postorder:-
- Traverse the left subtree.
The left subtree inturn might have left & right subtrees.
 - Traverse the right subtree.
The right subtree might have left and right subtrees.
 - Visit the root node.

```

class Node:
    global r
    global l
    global data

    def __init__(self,l):
        self.l=None
        self.data=l
        self.r=None

    class Tree:
        global root

        def __init__(self):
            self.root=None

        def add(self,val):
            if (self.root)==None:
                self.root=Node(val)
            else:
                newnode=Node(val)
                h=self.root
                while True:
                    if newnode.data<h.data:
                        if h.l==None:
                            h.l=newnode
                        else:
                            h.l=h.l
                    else:
                        h.r=newnode
                        h=h.r
                    print(newnode.data,"added on left of",h.data)
                    break
